

Atlantic Meridional Transect

The AMT programme has run since 1995, conducting multidisciplinary research during the annual return passage of Royal Research Ships (either *RRS James Clark Ross* or *RRS Discovery*) between the UK and the Falkland Islands or Cape Town, every May and September. This has provided a unique set of repeated measurements along a series of Atlantic meridional transect, covering a distance of almost 13,500km and a wide range of ecosystems.

RRS James Clark Ross

AMT8 cruise track

The first phase of the AMT programme took place between 1995 and 2000 and consisted of 12 cruises. BODC has been integrating data from the physical, chemical and biological measurements made on these earlier cruises. Data sets include:

Vertical CTD profiles

Optics casts

Continuous underway data

Biogeochemical measurements on water samples including nutrients, pigments, phytoplankton abundance and taxonomy, primary production, and dissolved gases

Zooplankton abundance and taxonomy from net hauls

The second phase of the programme (2002-2006) consisted of 6 cruises and involved 45 investigators, researchers and students from 7 UK partner institutions (Universities of Newcastle, Plymouth, Liverpool, Southampton and East Anglia, together with the Plymouth Marine Laboratory and the National Oceanography Centre, Southampton), as well as other national and international collaborators.

Objectives:

1. How does the structure, function, and flow of food within planktonic ecosystems vary in space and time?
2. How do physical processes affect the supply of nutrients, including dissolved organic matter, to the planktonic ecosystem?
3. How do ocean-atmosphere exchanges and sunlight affect the formation and breakdown of organic matter?

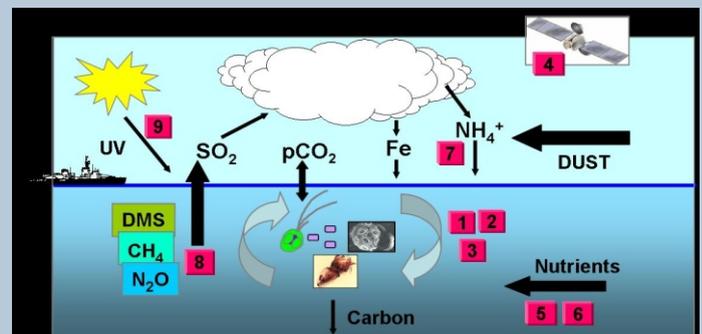

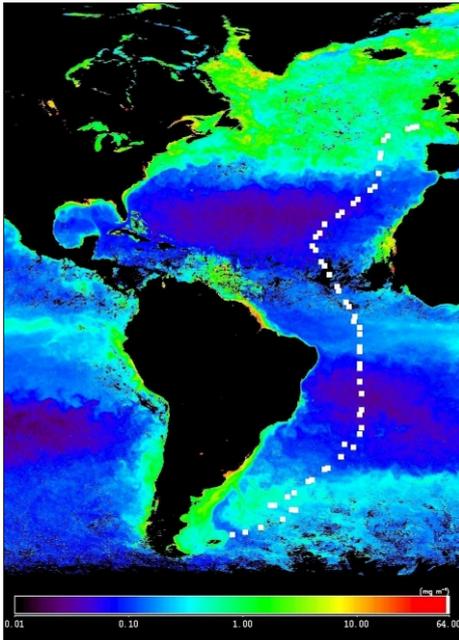

Diagram representing the foci of AMT research

These questions are being researched through the testing of nine hypotheses. More detail on these may be found on the official AMT website, <http://www.pml.ac.uk/amt/index.htm>

In the later phase of AMT, work focused on cross-disciplinary studies of ocean plankton ecology and biogeochemistry, and links to atmospheric processes.

When added to the observations from the 1995-2000 phase of the AMT programme, the work provides a unique ten-year time series of data, allowing some of the first detailed comparisons to be made of how ecosystems function in the North and South Atlantic gyres (circular current systems in the ocean).

The data sets collected during the AMT cruises between 2003 and 2006 include:

Aerosol and rainwater composition

Surface water time series and profiles of biological, chemical and physical parameters

Primary, new production and respiration measurements

Optical characteristics of the water column

Satellite imagery

Plankton community structure

BODC's work involves collating all of the AMT data sets from both phases into a quality-controlled integrated database.

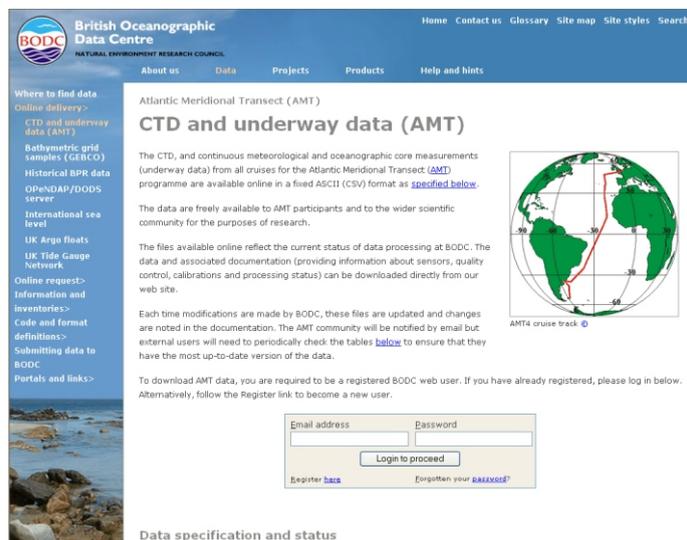

The data are assembled in a relational database, which links all samples through their time and position. This ensures that data are readily available for temporal and spatial studies.

CTD deployment

Zooplankton nets

The screenshot shows the BODC website interface. The main heading is "Atlantic Meridional Transect (AMT) CTD and underway data (AMT)". Below this, there is a globe icon and a "Data specification and status" section. A login form is visible at the bottom, with fields for "Email address" and "Password", and a "Login to proceed" button. There are also links for "Register here" and "Forgotten your USERNAME?".

AMT data management is tailored to meet the needs of AMT scientists where possible. Core oceanographic data sets, including profiles and time series, are processed, quality-controlled, and made available to AMT participants and the wider scientific community via the BODC web pages (<http://www.bodc.ac.uk/projects/uk/amt/>).

The AMT data policy has been designed to make the data available to the wider scientific community as quickly as possible, so that the maximum use may be made of this valuable data resource.
