S. McCully

J. Silva

R. Bush

B. Mulligan

M. Nicolaus

**DURATION:** 16 March – 29 March.

**LOCATION:** Western Channel (ICES area VIIE)

**NARRATIVE:**

There were a number of difficulties prior to sailing starting with the hire cars. They were not fit for purpose and Pat has recorded the problems. I have also e-mailed Jo Page but I see little in the way of progress. We have been talking about re-tendering for a while, just talked! Also none of the EDC pens supplied by SIGS as spares were working, so we would have had to sail with two spare pens if Richard had not managed to fix some of those from spare parts by cannibalisation.

We sailed on the 16th at 8:30 in the morning after offloading frozen samples and fish from the previous two cruises. On the first day we managed no more than the shake down tow off Travose head, due to the distances involved. We caught a good number of sole, plaice and lemons off, but collected no otoliths as this is not part of the cruise area. There were quite a few south coast beamers in the area obviously also taking advantage of some good catches.

On the 17th we started the survey proper just west of the Scillies. The OLEX paid off immediately saving us quite a bit of time trying to figure out where we could shoot. From there we headed further west picking up all stations in Stratum 1 followed by a 3 further stations in Stratum 8. This was a long day to midnight, because the forecast had not been looking good. Catches consisted mainly of megrim, a few monk and sole and benthos. Manuel has been photographing his litter samples, but there isn't very much at the moment.

On the 18th the weather started to turn quite rough, justifying the extended hours the previous day. We started at 8am to give people a bit of time to recuperate from the late night and to sort some technical glitches with the balances. Fishing north from about mid-channel into mounts bay, catches continued to be generally small but diverse with a few rays thrown in. There were some good catches of sole and lemons inshore and an abundance of small monks over the area as a

whole. Little in the way of fishing activity was noted in the area. Bill started processing the fisheries acoustic information, but cannot do much with the multibeam data because we were unable to get access to the Claris dongle.

The 19<sup>th</sup> saw us finishing sampling Stratum 2 in Mounts Bay and heading east to the area off Falmouth. The weather was improving so we could make decent progress, but managed only 7 stations because of the long transit distances. Catches represented the typical inshore fauna, with some large hauls of small cuttlefish, though fewer of the large ones usual for this time of year. A small number of cod were encountered in this area, but significantly more than is usual for this survey. No fishing activity was observed. On the last couple of tows of the day I noticed that there were a number of tows quite close to previous tows. In most cases this was coincidental due to the higher sampling density, but for some tows it seemed the identical microgrid had been selected to the previous year. Unable to locate the reason for this a new random selection was made for the remaining strata and a new survey plan developed rather than going through last years data and figuring out which of the positions had been selected before.

The following day we moved further east fishing from the Eddie Stone to start point. Stations are much closer in the area because of the higher sampling effort so we managed to get 9 tows in. Towards the end of the day there were some good catches of plaice in the area, something that had been lacking the previous year also sole started to be more abundant, with the usual by-catch species.

Fishing continued off the start on the 21<sup>st</sup> picking up stations mainly in strata 4 and 5, with good catches of sole, plaice monk and lemons, with some very good ones towards the end of the day. Catches were relatively clean but picking up a lot of flustra on occasions. Little fishing activity was noted in the area, but a couple of the Brixham beamtrawl fleet made an appearance, but mostly transiting through the area.

On the 22<sup>nd</sup> we started off start point and fished into Lyme Bay. Still some good catches of plaice in the morning with decent amounts of sole, but these petered out in the top of the bay being replaced by the more inshore species such as sullenettes and scald fish. We had some interactions with a number of inshore crabbers and trawlers, mostly amicable and helpful. We had been provided with the information on the local trawling agreement by Plymouth SFI and this made it much easier.

We started the following day off Portland collecting the last two stations on the English coast in stratum 5 before heading south through mid channel to the area between Guernsey and Alderney. We abandoned sampling one station just to the west of Alderney, when it became apparent that the ground was too rough to fish it effectively. Again the Olex made the process of determining possible locations significantly easier. From the start of the day we started to see larger numbers of spider crabs and good numbers of gurnards particularly streaky and tubs, also some nice brill and plaice, finishing the day on a large catch of sole on some sandy bottom. A couple of French trawlers were observed circling some of the local banks, but little in the way of static gear which had been present in previous years.

The 24<sup>th</sup> started with some good catches of sole and plaice, but numbers declined as we made our way around the Channel Islands southwards. Also caught were very substantial numbers of spider crabs in the area and some black sea bream usual for stratum 11. Further southward the static gear became very heavy and most of the clearer places were pretty uneven. There had been a number of stations already abandoned on along the east coast since the waters are too shallow to even pass east of Gurnsey. The last station of the day produced some more sole near the Bay de Mont Saint Michelle. On further station planned had to be left till day light because of static gear.

We started the 25<sup>th</sup> outside the Bay de Granville in amongst some potters and netters where we only managed to tow just over a mile due to a combination of static gear and poor grounds, and

even then there was little worth speaking of in the haul. The rest of the day was spent dodging brittle stars around the central basin. Station 8 could not be fished at all so we abandoned it for an alternate site the following day. Towards the afternoon we moved west towards the banc de langustine. There was some beaming activity to the east of the bank, but two netters had essentially monopolised the entire area with gillnets. Our stations were slightly to the south of this and we managed to collect our samples. There were more brittle stars, but also some sole seemingly on their way to spawn.

The morning of the 26<sup>th</sup> started in some swell and was forecast to get worse so we started at 5am with the water sample over the Hurd deep and proceeded north to pick up stations in stratum 9 and the remaining ones in 7. Catches consisted mainly of monk, and cuttlefish and some sole. Heading further south back to the west coast of Guernsey we managed to pick up the alternate for the one dropped the previous day, but could not find a suitable tow for the last station in stratum 11. This stratum has continuously caused difficulties and with the large number of brittle stars and pots the station had to be abandoned without replacement. The day finished with a large hauls of brittle stars having survived some pretty rough seas. Everyone is tired now.

The last day of the random survey started in some turbulent seas, but with sunshine out mid channel picking up the last station in stratum 9 under freshening winds. Heading into stratum 12 where generally the ground is quite rocky, we started to pick up more rocks than fish so the second tow was cut shorter to ensure the rocks did not pierce the cod ends in the increasing swells. It seems we have collected more sharks in the off shore region than in previous trips. Finishing on some more sandy tows with good number of monks and cuttlefish we completed the survey grid, just before crossing back into the UK sector.

The final day was a late start after giving the wet lab staff a bit of time to recover following a number of long days. It was spent fishing in Mounts Bay, where we had been having some trouble with the random grid selection. We collected a further five samples with good numbers of sole and monk as well as some plaice, roughly confirming the composition of previous samples. It will be interesting to see if it is possible to determine within stratum variance estimates from these greater number of samples.

#### PRIMARY RESULTS BY AIMS.

1. To carry out a beam trawl survey of the Western Channel for stock assessment purposes using standardized 4m beam trawls in order to obtain information on:
  - a) Distribution, size composition and abundance of all fish species caught.

#### Results:

A total of 85 stations were successfully sampled using the beam trawl gear spread over the 13 strata. Station numbers (including profiler / ctd samples) are shown in Figure 1 and presented in Table 1 with the cruise track and validity codes for the beam gear shown spatially in Figure 2. Total catches by species can be found in Table 2.

The general species composition by station scaled to the total catch in numbers as spatially represented pie charts is shown in Figure 3. For species of commercial importance separate distribution maps are shown in Figure 4 and comparisons with previous surveys for sole and plaice are depicted in Figure 5 and 6. Of interest is the spatial distribution of plaice, which were entirely absent from the French coast last year, but seem reasonable represented here in 2010.

b) Age – length distribution of selected species.

Results:

Length distributions were collected for all species of fish and a number of select shellfish species. Length distributions for the major commercial species encountered in the survey are shown in Figure 7 and comparisons with the length distribution of previous surveys for sole and plaice are shown in Figure 8 and 9.

c) Distribution of fish in relation to their environment.

Results:

Temperature and salinity and meteorological data were recorded for each haul, as well as acoustic information on seabed type and bathymetry collected and stored in raw data formats for later analysis.

d) Distribution of macrobenthos

Results:

Presence and absence were recorded for macrobenthic fauna at each station from the starboard gear, and key indicator species were weighed and enumerated.

e) Length weight & maturity information using individual fish measurements, in support of the EU Data Regulation.

Results length weight information was collected on all the major species up to a total of about 500 specimens per species. A total of 6868 samples were taken in addition to the length weight information provided by the 2167 otolith samples (Table 3).

2. To collect fisheries acoustic data at three operating frequencies (38, 120 & 200 kHz) and multibeam data continuously throughout the cruise. An attempt will be made to use this data to determine habitats and the scale at which these vary.

Results:

Fisheries acoustic data was recorded and processed on board in the hope of being able to link some of this information with the species composition and make some inference about the composition of species in areas not sampled. Multibeam data was also recorded and stored on the OLEX system.

## **SECONDARY RESULTS BY AIMS:**

1. Collect length weight information for DCF work (Ian)

Results:

A total of 6868 length weight data were collected. Table 3 shows the split by species.

2. Tag rays not needed for DCF maturity work (Joana undulate, cockoo, common skate and blonde ray)

Results:

A total of 31 rays were tagged and released.

3. Collect radiology water samples for Trevor Bailey (Sophy AE001)

Results:

Eleven water samples for radiological analysis were collected.

4. Collect Sardine and Anchovie samples for otolithing practice (Bill)

Results:

Few sardine or anchovies were caught during this survey. The ones collected were frozen for analysis at the lab.

5. Use and evaluate the litter evaluation protocol where time permits (Manuel SLA26)

Results:

A total of over 600 individual objects of anthropogenic origin were collected, photographed and described.

6. Collect maturity photographs for DCF (Rob)

Results:

Thirty six maturity photographs in accordance with the new guidelines from the recent maturity workshop were collected for a total of six fish with ancillary information on gonad weight and length.

Figure 1: Chart of station numbers for CEND 6/10 including profiler stations:

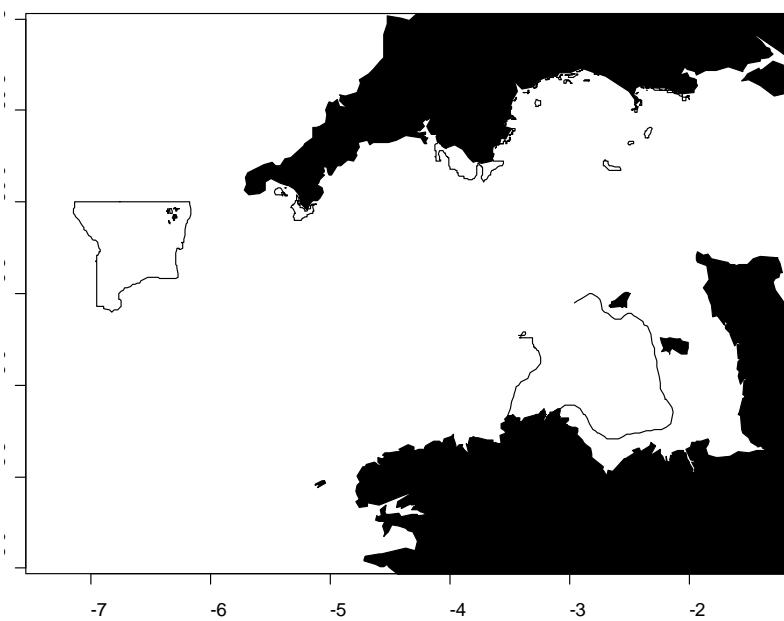

Figure 3: Species composition in number by station, circle radius proportional to the square root of the total number of individuals with angle proportional to the number by species.

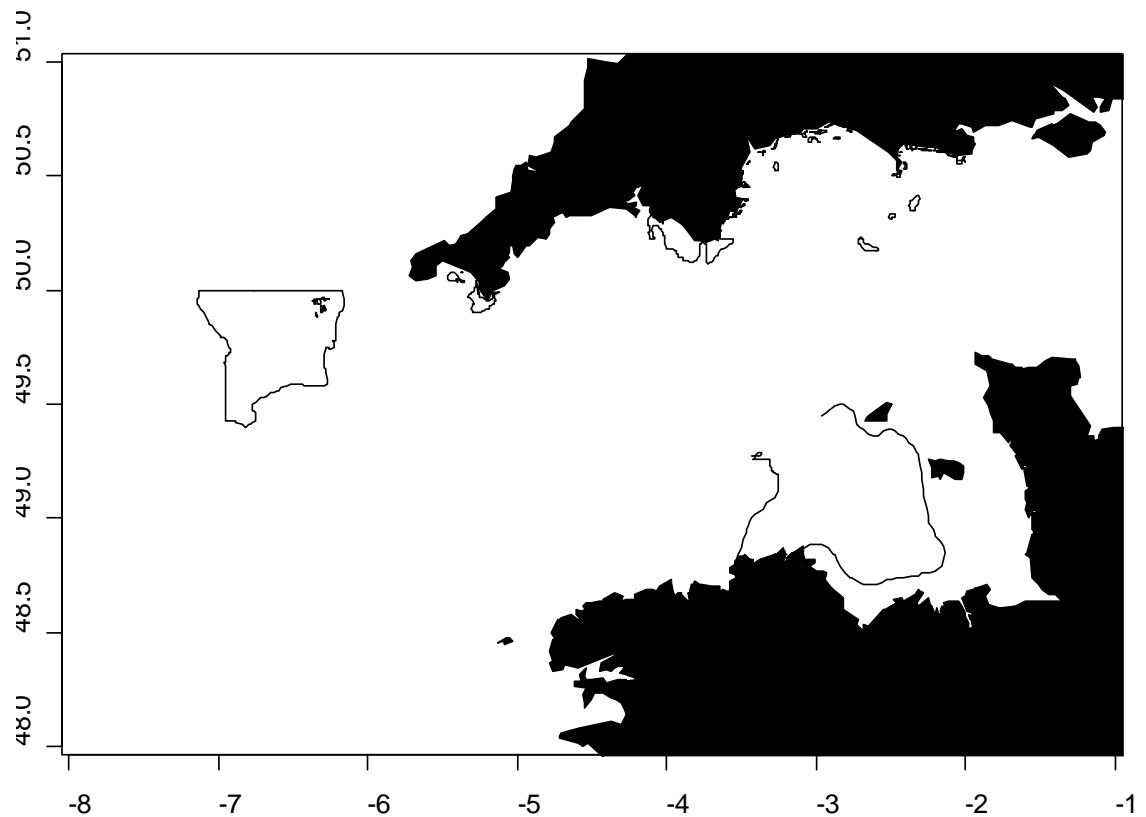

Figure 4: Distribution of major commercial species by station

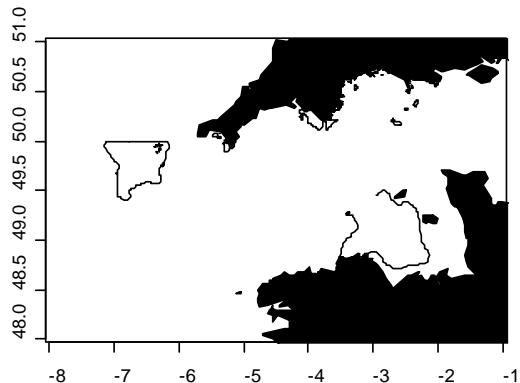

Figure 5: Timeseries of sole distribution, note that the size of bubbles is not to the same scale.

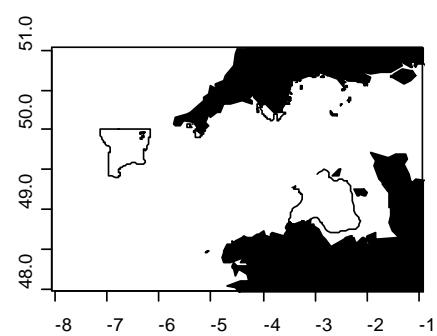

Figure 6: Timeseries of plaice distribution, note that the size of bubbles is not to the same scale.

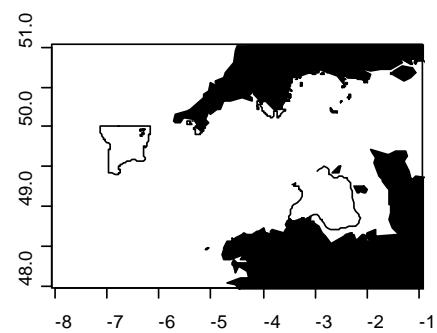

Figure 6: Length distributions for the major commercial species with total catch numbers by the two different gear types.

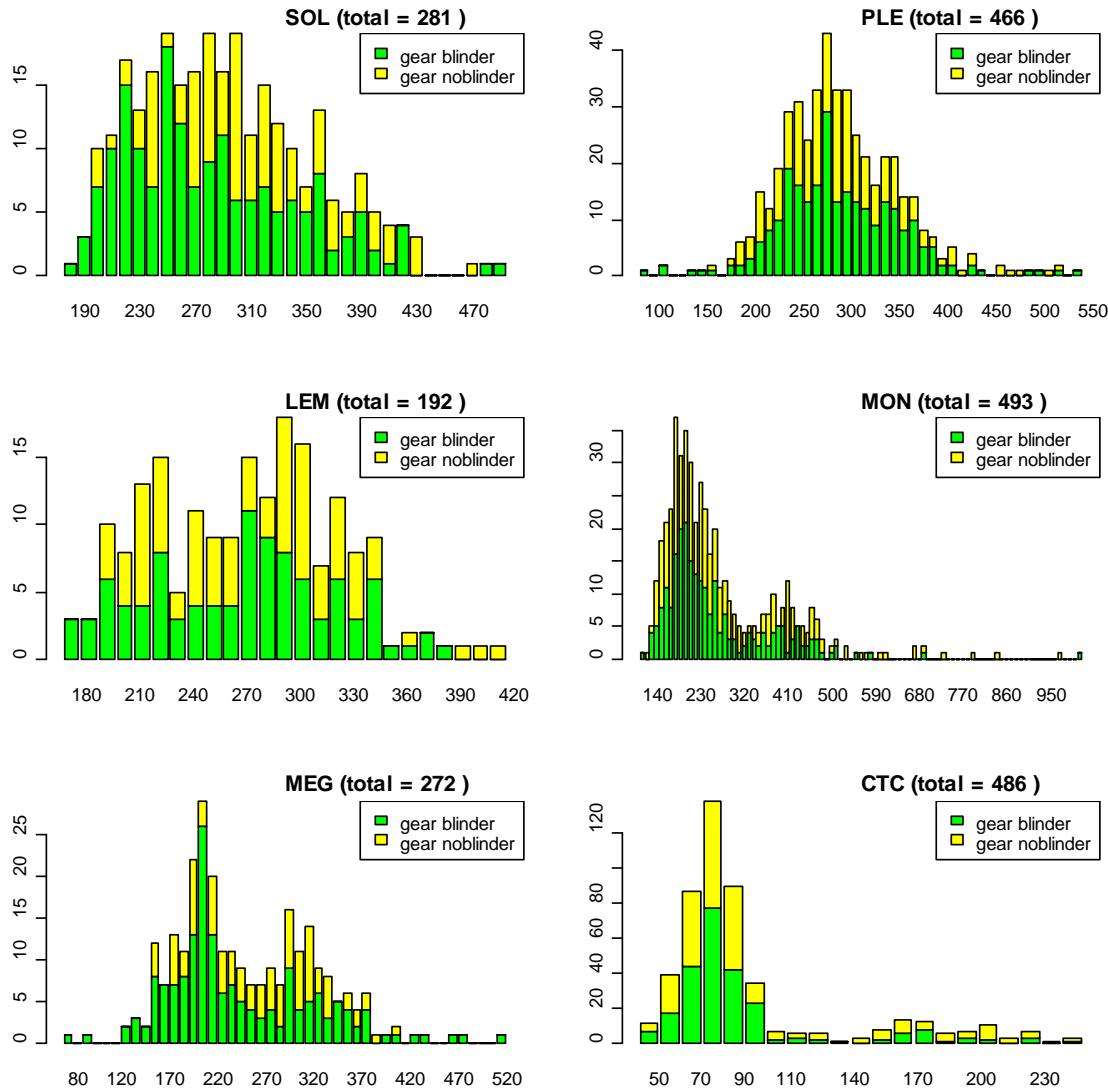

Figure 8: Timeseries of sole length frequency distributions by the two different gear types. Note that in 2010 five additional stations were sampled in stratum 2.

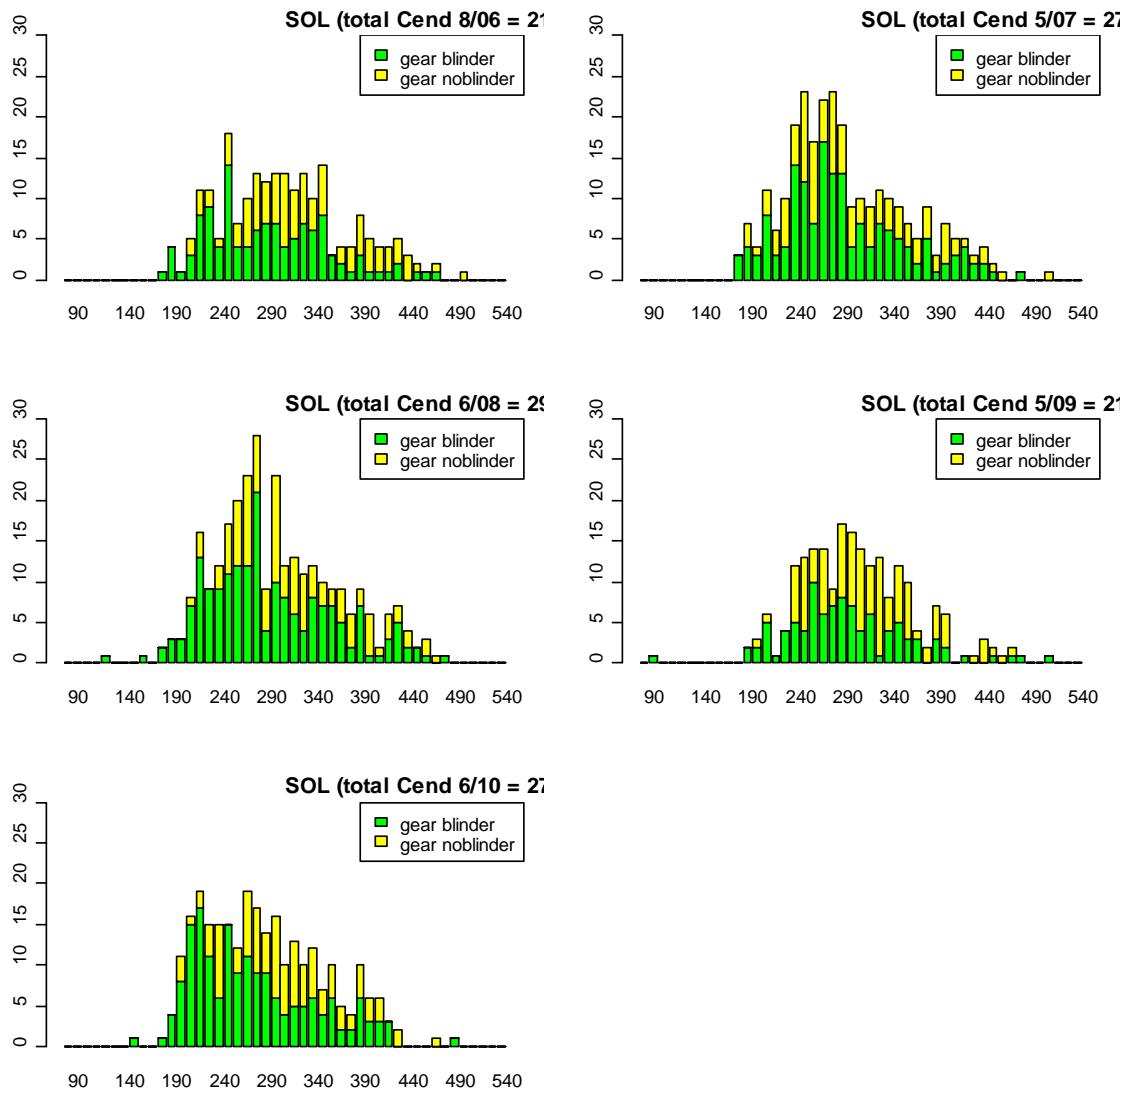

Figure 9: Timeseries of plaice length frequency distributions by the two different gear types. Note that in 2010 five additional stations were sampled in stratum 2.
