DURATION: 22 March - 4 April 2006
LOCATION: Western Channel Portland to Scilly Isles in UK, French and Channel Island waters.

AIMS:

## NARRATIVE:

The CEFAS Endeavour sailed from Portland at 10:30 on the $22^{\text {nd }}$ of March to commence the CEND 8/06 survey of the western Channel. The new gear was inspected on the way to the first station. Small modifications to the dog-ropes were required for use on Endeavour. (Towing chain certificates were not received, and enquiries need to be made as to the necessary certificates). Sampling started in stratum 6 at 14:00 amongst strong northerly winds completing 2 stations on the first day as crew and scientist were accustoming themselves to the new gear arrangements. Beam 1 was towed on the port side fitted with the 40 mm blinder with the CTD attached (Gearcode 101530402). The starboard beam (Beam 2) was fished using just the commercial 80 mm codend supplied by the manufacturer (Gearcode 101530503). Tagging work was carried out in Lyme Bay during the dark period ( 30 min tows) with 40 sole successfully tagged.

## Defects:

The only spare supplies for the beams were an additional beam fully fitted, an additional trawl, and one codend. No separate panels, chains or shackles (these were kept from the previous cruise) were available and these will need to be sourced prior to commencement of next years survey.
The chemical storage box kept on deck was full of water without any provisions for emptying. Additionally there seemed to be more chemicals present than required for the current cruise.

Continuous water sampler was not working. It was working on the previous cruise and I was told I would not have to do anything to it. It appears just to have been switched off.
The multi-beam was not functional as the external harddrive was lost without any error reports from the software. If this had not been noticed the raw data to the entire cruise could have been lost as appears to be the case for the last stations of the previous cruise. Storage was restored by a complete system reboot. Control of the multi-beam from the bridge would have been preferable as it required personnel to leave the fish room or bridge to set surveys. Helmsman 4 (aft wheelhouse) monitor was not functioning. No water bottles supplied as per gear list.

On day two 9 stations were sampled in Lyme Bay and off Start Point, mostly positioned in stratum 4 with winds increasing to gale force. Small numbers of sole and reasonable numbers of plaice were encountered. Weather conditions were too severe to continue tagging at night.

On the $24^{\text {th }}$ of March sampling continued from Start Point to Falmouth Bay with a further 9 stations completed. The gear performed well and discussions with the crew, Bob Rogers and Dave Murphy indicated the gear was satisfactory for the survey and that low survey catches of sole appeared to be the result of low abundance on the ground rather than the gear. Tagging was attempted during the hours of dark near the Eddy Stone, but few sole were caught

After completion of a further six stations in Falmouth Bay on the next day the Endeavour headed to Falmouth to drop off Bob, whilst awaiting the return of the launch the drop keel deployed due to the parting of a block. The remaining survey time in the afternoon was spent making emergency repairs to facilitate the continuation of the cruise. Increasing winds made tagging operations impossible.

On the $26^{\text {th }}$ of March 6 stations of Falmouth were sampled in stratum 3 and 8, with few fish encountered. Imminent gale force winds forced a return to Falmouth in the afternoon (about 17:00).

## Defects:

A lack of cup holders and better rails on the SIC table on the bridge could have prevented a serious spillage of coffee on the bridge.

The $27^{\text {th }}$ of March was spent on anchor in Falmouth due to winds in excess of 40 knots.

The following day the Endeavour weighed anchor at 6:00 heading west to Mounts Bay to sample stations in the inshore sector in rough conditions. The decision was made to continue out towards the Scilly Isles despite poor conditions. 7 Stations were completed, the last of which were located south of the Scilly Isles. Tagging was attempted south of the Scilly's but only six sole caught and tagged.

On the $29^{\text {th }}$ the sampling commenced at the eastern edge of the sampling grid near the 2 degree line, swinging south east to complete stations mid-channel in rough conditions. Two further stations were sampled during the dark period as distances
were too great to complete these during daylight hours given the length of the survey. Consequently no tagging was attempted.

The following day the remaining mid-channel stations were completed, dipping into French territorial waters east of Guernsey heading to the Langoustine Bank in the afternoon. Abundance of soles increased on the edge of the Hurd Deep, and some activity of Brixham beamers was observed in the vicinity. Six sole were tagged near the Banks during the night. The decision was made to scrap three stations on the western edge of stratum 12 as there was insufficient time to sample these with the transit distances involved.

## Defects:

The protective boards recently fitted in dry dock came away on the port side. One board was lost, with the others being recovered to prevent further losses).

On Saturday sampling started on the French coast (strata 11 and 10) on unknown tows. Tides were generally severe although weather was improving. The ground was extremely rocky and three tows had to be repeated due to codend damage. Stations with invalid tows were repeated for a 1-mile rather than the usual 2-mile tows. Few soles and little fisheries activity was observed in the area. 19 soles were tagged during the night-time, before moving along the coast for the next days sampling.

On the $1^{\text {st }}$ of April sampling continued on the French inshore stations with heavy catches of ophiuroids on several of the stations near St Marlo. Few soles encountered until the last stations on of the day (Station 703), on which 14 soles were caught. 96 soles were tagged in the area of 703 during the night.

On Sunday sampling continued northwards along the French coast and amongst the Channel Islands. Lots of sea-horses and spider crabs encountered on two stations, but few soles. No tagging was possible due to very strong tides.

## Defects:

Towing chain of the port side beam caught on the remains of the structure holding the protective boards. This created slack on the winch drum when the warp was paid out. Winch problems were resolved and offending structure removed.

Sampling of the final day ( $3^{\text {rd }}$ of April) commenced at 7:00 hours as the tides near the Race of Alderney were very strong and trawling was only possible during slack water. After completing two further stations all sampling was complete and the Endeavour headed back for Lowestoft docking at lunchtime on the $4^{\text {th }}$ of April.

Results for main aims:
A total of 76 survey stations were sampled with 80 completed hauls and 77 valid tows for each of the two gears. Table 1 indicates the number of samples collected by stratum and gear code. Strata $4,5,10$ and 11 were sampled more intensively than other strata as they are thought to contain the main fishing grounds of the French and UK fleets exploiting dover sole in division VIIe. Location of samples is indicated in Table 2 along with times and ICES rectangles sampled.

Length distributions for each of the major commercial species are shown in Table 3 and graphically displayed in Figure 1-3 for the three major commercial species. Catches of monk (216), sole (118 female; 89 male) and plaice ( 260 female; 96 male) were spread over a wide range of lengths, but only a small number of small sole were encountered. Numbers of otolith and maturity stages taken are indicated in Table 4. Otoliths were taken in three strata (Uk inshore, French inshore and mid-channel) with most commercial specimens taken for EU-dataregs species.

Tagging operations carried out at night provided 176 tagged fish released near the location of capture. Unfortunately most sole tagged were larger than the juvenile stages that we had hoped to tag, but the number of small sole caught in the survey as a whole indicated that there were few sole of that size available for capture in the areas that could be sampled. Figure 4 shows the length frequency of soles tagged with release positions, length, and weight for soles tagged shown in Table 5.

Additional aims:
Multi-beam information was collected for all 80 samples taken, but unfortunately weather and light conditions did not permit the deployment of the underwater camera for groundtruthing.

Length frequency information for spider crabs was collected in 10 mm increments. Unfortunately it was not possible to collect information in the 5 mm increments as requested, as the EDC had been set up for 10 mm increments and it was not possible to change the set up. All spider crabs caught were measured.

Berried female edible crabs were sampled for genetic analysis. Only 16 samples were taken as only 16 sample vials were provided.

Shell samples were collected for micro chemistry analysis at each of the stations and frozen immediately.

Squid samples for genetic analysis for each species encountered were collected and frozen. No alcohol or vials had been provided.

No four-spot megrim fin clip samples were collected as no specimens were encountered. Sand sole samples had been completed on the previous cruise.
