Abstract

Four SeaSoar surveys were carried out from FS *Polarstern* during the ANT XIII/2 cruise, to look at upper ocean dynamics in areas of high biological productivity. As well as the standard CTD (conductivity, temperature, depth) measurements, the SeaSoar was fitted with a fluorimeter and Optical Plankton Counter (OPC), the latter being used for the first time. This report describes in some detail the methods used to reduce the OPC data and presents the data contour plots and profiles, section by section, without interpretation. The data are presented using the manufacturer's default conversion tables from particle size to equivalent spherical diameter. More accurate calibration awaits analysis of zooplankton samples.

Introduction

ANT XIII/2 was the first cruise on which the SeaSoar was fitted with an Optical Plankton Counter (OPC). A team from the Southampton Oceanography Centre (SOC) participated in this cruise by kind invitation of Dr V Smetacek of the Alfred Wegener Institut für Polar- und Meeresforschung (AWI). This report describes our first experiences, the programs and execs developed to process the data and presents the data collected but as yet uncalibrated against net samples.

The OPC-1T optical plankton counter was developed at the Bedford Institute of Oceanography (Herman, 1992) and is manufactured by Focal Technologies Inc. The instrument used on SeaSoar (serial number TOW026) was purchased in 1995. It was fitted with an acrylic flow insert to reduce the tunnel cross-section to 0.001 m² for towed use and was mounted beneath the SeaSoar in place of the usual torpedo shaped weight. No problems were experienced, but it appeared that the extra drag somewhat limited the maximum depth that could be reached with acceptable cable strains. Profiling on AntXIII/2 was usually down to 350 - 360 m but had to be limited to 300 m on occasions when the cable termination was beginning to fail. The cable connection out of the rear of the OPC was vulnerable to crushing during deployment and recovery when the SeaSoar was being lifted out of or placed into its stand, also when the SeaSoar and stand were being moved around the deck. However, no failures occurred.

The OPC estimates the equivalent spherical diameter (ESD) of particles that break the 640 nm LED light beam. ESDs between 250μ and 3mm can be resolved. However, for calibration and interpretation it is essential to collect net samples of zooplankton and possibly to use a laboratory version of the OPC to investigate how it responds to the shapes and translucence of the zooplankton sizes and species observed. On AntXIII/2, Corinna Dubischar of the AWI was using a second OPC mounted on a 5-sample multinet to obtain calibration samples during station work. These will be analysed and used in due course to calibrate the data introduced here. However, in this report all data are "calibrated" only by using the reference calibration table given in the OPC handbook.

The SeaSoar, OPC and associated computing were installed on the *Polarstern* in Bremerhaven prior to the cruise. Details of operations are given in the associated SeaSoar data report (Griffiths *et al.*, 1996), where a diary of deployments is also given. A summary only is presented here. Details of the meteorological conditions may be found in the Underway Data Report Read *et al.*, 1996) and Acoustic Doppler Current Profiler Data are presented in the ADCP Data Report (Allen *et al.*, 1996)

There were three main deployments of the SeaSoar/OPC system on the cruise (Tables 1 and 2, Figures 1-3), a long transect on passage from Cape Town to Antarctica, a Course Scale Survey (CSS) and a Fine Scale Survey (FSS). The long transect, spanning 15.5° of latitude from 41°47'S, 12°46'E to 57°19'S, 2°06'W on passage to the German Antarctic base at Neumayer, was split into Runs 2 and 3 (Table 1, Fig. 1)) by a break for an attempted mooring recovery near 50°S. On return from Neumayer, part of the transect was repeated as Run 6.1 from 54°S to the mooring position, and Run 6 continued with the Course Scale Survey of 6 north-south legs (Table 2, Fig. 2) 75 km apart to choose an area for a fine-scale survey. After three days pause for station work, the Fine-Scale Survey consisting of 11 north-south legs 13 km apart was undertaken in the northeast corner of the CSS area (Table 2, Fig. 3). The significant difference between the two surveys was that the 75 km separation of legs on the CSS was too large to resolve the small to meso-scale eddies (tens of km diameter) that are most likely to be responsible for plankton patchiness. Indeed, the plots show major, barely mappable changes from leg to leg of the CSS.

Data analysis

The OPC data stream

Logging of OPC data is significantly different from previous physical PSTAR data streams, in that the number of data values per second is highly variable. Every time a particle enters the OPC light beam, its size is recorded, given as an integer between 0 and 4095 related by a nominal calibration table to the ESD. The specification of the OPC is that it can sample up to 200 counts per second, but in practice it may saturate at rates over 100 counts per second. When towed under the SeaSoar at 4 m s⁻¹, the acrylic insert is used to reduce the counts per second.

On Ant XIII/2 counts varied typically between 0-10 per second below 100 m up to nearly 100 per second in the surface layer. Thus the sampling rate was high, on average 50 counts per second. In addition to the size of each particle, the OPC normally logs two other variables, a pulse from the pc's internal clock twice per second, and light attenuation also twice per second. The former provides a crude time base. The latter is monitored by the OPC so that it can constantly adjust the intensity of shadow that it recognises as a valid particle passing through the beam. Each of the three variables (count, clock and attenuance) is stored in 12 bits of a two-byte output word, the remaining 4 bits specifying which variable follows.

The time base provided by the internal clock is inadequate for SeaSoar operations, because the pc clock can and did drift by a second or more every 1 to 4 hours, yet time must be used to correlate the OPC data to the SeaSoar data, where the SeaSoar is profiling through the water column at rates up to 1-2 m s⁻¹. For this reason, the OPC suppliers were requested to make provision in the software for logging an additional time variable, an RS-

232 serial WEMPE clock stream in the NMEA-0183 format provided on *Polarstern*. This clock was also interfaced to the SeaSoar data stream, so providing the master time base for all data logged on the cruise. The clock data were inserted in the OPC data stream once per second as a 27 character ASCII string starting and ending with an ID serial byte 'C0' (hex).

A second clock option, to match the RVS clock format, was also provided by the manufacturers, but has not yet been used.

File transfer from the OPC pc to PSTAR computer

OPC data are normally logged to the pc hard disc in a continuous stream, which can only be read back later when data logging ceases. To avoid this, PC NFS software was added to the pc and data were logged over the ethernet to a hard disc partition on the PSTAR computer. This caused loss of about 20 minutes of data on one occasion when the emergency power switch in the PSTAR laboratory was accidentally knocked, but otherwise was entirely satisfactory. To avoid excessively long files, the switches to stop and start data logging on the pc were toggled once every 4 hours by a watchkeeper and the times noted to the second. For convenience, this was done one hour into each watch at the same time 4-hourly SeaSoar processing started. This procedure automatically started a new raw data file each time, updating the extension to the file name .Dnn from .D00 through .D01, .D02, etc. (For file naming conventions, see Appendix 1).

Two programs were written to read the raw data into PSTAR, POPCIN and a minor variant, POPAIN. A listing of POPCIN is given in Appendix 1. The major problems in these programs were (a) to resync when bad data are found in the data stream and (b) to create a time base. To establish sync for the WEMPE clock used on *Polarstern*, the program searched for two bytes 29 bytes apart and both containing 'C0'. The 27 byte string inbetween could then reliably be taken to be a clock string. Data of type 1 (target size) for POPCIN or type 2 (light attenuation) for POPAIN were then read into a buffer until a second clock string was found. A time base was then created by arbitrarily assuming that the targets (or light attenuation values) were evenly spaced in time between the two clock times. The times created are thus correct to a fraction of a second.

POPCIN and POPAIN will need to be modified for used with the RVS clock when used on an RVS ship.

These programs also contain code to use the pc's internal clock, which increments by 1 every 0.5 seconds and resets to zero when it reaches 4095. This code was tested during the trial Run 1 of SeaSoar when the WEMPE clock was not being logged. (This occurred because it was found that the WEMPE clock was not logged when a mouse was fitted to the pc.) However, these data were not processed further, so the code for the internal clock has not been exhaustively tested. If the internal clock has to be used, it should be possible to establish a time base accurate to a second by accurately noting the times when logging to file is started and stopped, then using pcalib to stretch the time base as necessary.

Further information on POPCIN and POPAIN and on running them in OPCEEXEC0 is given in Appendix 1.

Further processing and data reduction

The 4-hour files created by POPCIN were large, typically containing 300,000 data cycles, hence the reason that only two variables (time and count) were stored, with the attenuation data (twice per second) read into a separate file. Nevertheless, these are the master files, in which no information is lost. Further processing, described here, separates the data into size classes and loses information in so doing. The size classes and averaging developed on ANT XIII/2 are cruise specific, and will probably need modification on future cruises. In particular, in oligotrophic areas, more careful averaging may be needed to separate the data into size classes over usefully small vertical intervals.

To proceed further, the OPC data must be merged (on time) with the SeaSoar CTD data to provide pressure and with navigation data to provide distance run (distrun). They can then be binned into pressure intervals (POPCAV) or gridded by binning on both pressure and distrun (PGRIDO). In both cases, the distrun variable is needed to calculate the volume of water that has flowed through the OPC in the binning interval, and hence to normalise the number of counts (total or in each size class) to counts/m³.

The 4-hourly files were therefore appended over 12 (or more usually, with overlap, 16) hours to match the 12-hourly SeaSoar processing and then pressure and distrun from the SeaSoar-plus-navigation file were merged onto the OPC file to create a file containing 4 variables and usually over a million data cycles. The slightly tedious part of this procedure was to truncate (relatively few) data cycles from the ends of the appended OPC file to ensure that its times lay within the times of the SeaSoar file. This was easy if logging to the 4-hourly OPC files had been stopped one or two seconds before the end of the 4-hourly SeaSoar processing period and restarted a second after the start of the next period, but it would have been unreasonable to expect watchkeepers to achieve this always. After appending and truncating, further processing was done within an exec, OPCEEXEC1 (see Appendix 1).

PGRIDO

PGRIDO was the first analysis program developed to provide a quick look at the OPC data split into a few size classes. The size classes chosen, 7-86, 87-686 and greater than 686 OPC units, corresponded to 250-1000 microns, 1-3mm and greater than 3mm using the default OPC ESD lookup table. These size classes are hard coded into PGRIDO and may need changing or generalising in future. PGRIDO is a relatively minor variant of PGRIDS, the SeaSoar gridding program. Both bin the data into particular depth and distrun ranges. However, where PGRIDS finishes by averaging the N data values in a particular bin, N is itself the output value for PGRIDO, divided by the volume of water that flowed through the OPC for counts in that bin. Of course, in addition to the total count N over all particles of whatever size, PGRIDO also calculates N_i (i = 1, 2, 3) for the three size classes chosen.

POPCAV

Given the typically large counts per second, it was later realized that data from a single profile could be binned over quite small depth ranges with better resolution of size classes than PGRIDO. Therefore POPCAV was written as a minor variant of PAVERGE (in the same relationship as PGRIDO to PGRIDS). As before, the normalized count N rather than the average is the output for each averaging interval. The size classes chosen were

again hard-coded into the program, and 5 were chosen corresponding to 250-350 μ , 350-500 μ , 500-800 μ , 800-1000 μ and greater than 1000 μ (1 mm).

POPCAV was applied to all the 12-hour files of OPC counts (plus time, pressure and distrun), binning on pressure into 2 dbar intervals. Given mean up and down rates for the SeaSoar of only 0.5 m/s, there were on average say 4 seconds of data per bin, so several hundred counts. Reducing these to 5 size classes thus reduced the file size by an order of magnitude or more. Thus a more versatile program, with more size classes, would still reduce the data greatly in a productive region. A significant advantage of using POPCAV is that the file of attenuation values can be merged on time onto the averaged file, and PGRIDS can then be used for gridding and contouring in the usual way. This has been done for the data presented in this report.

PLOTYX

One further program was developed to display OPC data, but can be applied to any data set. Where the standard PSTAR program PLOTXY can plot several y-variables against a single x-variable, PLOTYX plots several x-variables against a single y-variable. However, PLOTYX is more related to PLOTPR than PLOTXY in that it plots profiles of each x-variable, offsetting the profiles by one x-axis tick mark after each profile. Thus PLOTYX is a version of PLOTGR which can display offset profiles of several variables (in different colours) simultaneously. Thus profiles of several size classes can be simultaneously displayed. Equally, however, it can be used to plot SeaSoar CTD data in profile form just as CTD casts are plotted, but with many (small) multiple profiles per page.

Data presentation

Three track plots are presented first, for the initial long run (Runs 2 and 3), the Course Scale Survey (Run 6) and the Fine Scale Survey (Run 8).

All the remaining plots are matched on two facing pages. Two contour plots on the lefthand page show total particle density and attenuation. The small tick marks along the x-axis are the positions at which the data were gridded. The profile plot at the bottom of the lefthand page presents the profiles of total particle density at those grid points. On the righthand page are shown five sets of profiles, where the total counts have been separated into the five size classes shown. Note the change of scale between the top three plots and the bottom two. Note that the x-axis scale for the profile plots refers to the "first profile", which may be absent! The zero line for an individual profile may reliably be determined from the x-axis tick mark that is just to the left of the base of the profile, as the values are always close to zero (less than one tick interval) at the maximum depth reached.

Runs 2 and 3 are presented over 4 double pages, 4° of latitude per page. Run 6.1 is presented twice, first at 4° on the page to match Run 3 which it repeated, second at 2.7° per page to match the remainder of Run 6. The 7 legs of Run 6 are presented one per double page, all on the same latitude scale, spanning 2.7° from 49.4°S to 52.1°S. The 11 legs of Run 8 are presented one per double page, all on the same latitude scale, spanning 1.1° from 49.7°S to 50.8°S.

Acknowledgements

Much of the success in logging and processing of SeaSoar and OPC data during this cruise was due to the excellent pre-cruise advice and support received from the Ocean Technology Division and Research Vessel Services at the Southampton Oceanographic Centre. We would like to thank in particular Ed Cooper for his detailed reconnaissance, and John Smithers, Martin Beney and Alan Taylor for their help at SOC preparing equipment, and hard work setting up hardware on the *Polarstern* in a wintery Bremerhaven, in November 1995. Our participation was partially supported by the MOD under Joint Grant funding for FAME (Quantifying the structure of Fronts And Mesoscale Eddies).

Appendix 1 - Computing

Naming conventions

All OPC processing was done in directory /users/pstar/data/opc, which occupied a separate partition. Data names were all 8 characters long followed the convention ddcccnnn, where dd identifies the data type, ccc is the cruise identifier (set to 'ps1' - our first cruise on *Polarstern*), and nnn is a number incrementing from 001. The file names, and (usually) data names were thus:

- opa13r08.d24 for the pc raw data files. Here 'op' signifies OPC, 'a13' is equivalent to 'ps1' but was created before 'ps1' was chosen for the cruise name, 'r08' signifies 'run 8' and 'd24' is the file extension created by the OPC pc.
- o4ps1nnn PSTAR file for 4-hourly segments of raw OPC counts. Run 2 - 001-018; Run 3 - 019-031; Run 6 - 032-069; Run 8 - 071-094.
- oops1nnn PSTAR file for 4-hourly segments of raw attenuation. File numbers nnn match those for 'o4' files.
- oppss1nnn Appended 'o4' file 12 or 16 hours long. Run 2 - 001-005; Run 3 - 006-010; Run 6 - 011-022; Run 8 - 023-030.
- oppss1nnn.nav Same as 'op' files but with pressure and distrun merged on. Data name still oppss1nnn.
- atps1nnn Appended 'oa' file 12 or 16 hours long. File numbers nnn match those for 'op' files.
- atps1nnn.nav As for oppss1nnn, but for attenuation.
- oppss1nnn.av Created from oppss1nnn.nav files by POPCAV with 2 dbar pressure intervals.
- oops1rnns These files, one for each run (r02, r03, r06 and r08) were created by appending the '.av' files for each run, deleting overlaps, then merging in attenuation values from appended 'oa' files, one for each run. The data name matches the file name. These are the master files for the cruise covering total zooplanton counts, attenuation and 5 size classes. If further or different size classes are required, processing must be restarted from the 'oppss1nnn.nav' files.
- ogps1rnns Gridded files derived from oops1rnns by using PGRIDS with 8 dbar and 6 km bins.
- run6.block and run8.block were created from ogps1r06 and 08 by copying out each of the survey lines, sorting on latitude, regridding by horizontal linear

interpolation onto even intervals of latitude about 0.05° apart, then re-appending to form a 3-dimensional file stored in order pressure, latitude, longitude; i.e. section 6.1, section 6.2, etc.

run6.map and run8.map were created from the ‘.block’ files by using pinvxy to reorder the x, y and z variables so that they are in order latitude, longitude, pressure;; i.e. map at 5 dbar, map at 13 dbar, map at 21 dbar, etc.

Programs developed for OPC processing

POPCIN and POPAIN

These programs are most often run within OPCEEXEC0, where the detailed input requirements can be inferred. Each program asks for the name of the pc input file ('opa13 is hard coded and will need to be generalised on a subsequent cruise) and prints the ASCII header of that file so that the user can check if it is the correct one. The start time given by the pc's internal clock is the primary guide, so it is advisable to reset the pc clock from time to time so that it is accurate within a minute or two. If the start time matches the time when logging was started (read and written down from an accurate ship's clock), answer 'y' to the 'continue?' question, and enter the type of clock (WEMPE or internal), the output file name, the data name, and the accurate start time. On completion, the program lists the number of times that sync of the time base has been lost. This can be a guide to cable problems.

POPCAV

POPCAV is a fairly minor variant of PAVRGE. The input required from the user is identical. Variables named 'count' and 'distrun' must be present in the input stream. All variables are averaged in the normal way except count. Five extra output variables are created for the 5 size classes. The actual values of 'count' are used only to determine into which size class a particular data cycle falls. Output values are the number of data cycles in the bin normalised by the volume of water.

```

PGRIDO

PGRIDO is a relatively minor variant of PGRIDS, but only three variables, 'distrun', 'press' and 'count' must be given. Three extra output variables are created, for the three size classes that are hard-coded in. These three variables and 'count' are processed exactly as described under POPCAV above. Gridding input required is identical to that required by PGRIDS.

Execs developed for OPC processing

OPCEXEC0

```
#####
# opceexec0
#
# Description:
# This is the first exec in a series to processes OPC data at sea
# opceexec0 reads in the data from the PC binary file and converts it
# to Pstar format. It sets up the dataname and other header details.
#
# Files produced:
# o4$CRUISE$num Pstar format of data; only time and count because
# many data cycles
#   o4$CRUISE$num.arch archive copy of o4psl$num.
#
# Main processing steps:
# STEP_01      Read in data using datapup
# STEP_02      Archive
#
# History:
# Version Date      Author    Description
# 01              RTP       Original version.
# NEXT      ??/?/? ?? ??      Please make a note of your changes here
#                                - using as many lines as necessary. If
#                                the changes are substantial perhaps a
#                                new exec might be better?
#

Table 1

SeaSoar deployments on AntXIII/2

Run	start	time (Z)	day/date	latitude	longitude	distance run (km)
001	start	1347	339/5xii95	39°05.9'S	14°43.9'E	679
	end	1834	339/5xii95	39°38.8'S	14°15.0'E	753
	duration	4h47m		mean speed 8.3 kt		74 km
	Reason for recovery					End of trial
002	start	0931	340/6xii95	41°46.7'S	12°46.4'E	1036
	end	0300	343/9xii95	50°13.5'S	5°46.0'E	2127
	duration	2d17h29m		mean speed 8.9 kt		1091 km
	Reason for recovery					End of run - mooring position reached
003	start	1427	343/9xii95	50°21.3'S	5°31.3'E	2195
	end	2117	345/11xii95	57°19.5'S	2°06.3'W	3185
	duration	2d6h50m		mean speed 9.7 kt		990 km
	Reason for recovery					End of run - ice reached
6.1-3	start	1845	356/22xii95	54°00.6'S	0°05.8'W	6954
	end	1848	359/25xii95	50°28.2'S	8°05.3'E	8235
	duration	3d0h3m		mean speed 9.7 kt		1281 km
	Reason for recovery					End of run - station position
6.4-5	start	2240	359/25xii95	50°29.1'S	8°07.8'E	8248
	end	0930	361/27xii95	49°54.9'S	10°15.3'E	8844
	duration	1d10h50m		mean speed 9.2 kt		596 km
	Reason for recovery					Cable problem - need to reterminate
6.6-7	start	1715	361/27xii95	49°28.2'S	10°31.4'E	8903
	end	0845	363/29xii95	49°27.8'S	11°24.6'E	9555
	duration	1d15h34m		mean speed 8.8 kt		652 km
	Reason for recovery					End of survey
8.1	start	0900	001/1i96	49°41.5'S	11°19.8'E	10292
	end	1430	001/1i96	50°25.0'S	11°23.1'E	10376
	duration	5h30m		mean speed 8.2 kt		84 km
	Reason for recovery					Vehicle not flying - kelp holdfast around wing
8.1-11	start	1500	001/1i96	50°27.8'S	11°23.3'E	10381
	end	0627	005/5i96	50°48.6'S	9°30.0'E	11768
	duration	3d15h27m		mean speed 8.5 kt		1387 km
	Reason for recovery					End of survey
Totals						
	duration	15d4h30m		mean speed 9.0 kt		6155 km
